A QUASIFIBRATION OF SPACES OF POSITIVE SCALAR CURVATURE METRICS

VLADISLAV CHERNYSH

(Communicated by Alexander N. Dranishnikov)

Abstract. In this paper we show that for Riemannian manifolds with boundary the natural restriction map is a quasifibration between spaces of metrics of positive scalar curvature. We apply this result to study homotopy properties of spaces of such metrics on manifolds with boundary.

1. Introduction

The purpose of this note is to establish the fact that a natural restriction map in Riemannian geometry is a quasifibration of metrics of positive scalar curvature and discuss some applications to the study of spaces of positive scalar curvature metrics.

If $M$ is an open manifold, then, by a result of Gromov [Gro69], there always exists on $M$ a metric of positive sectional curvature. However, such a metric, in general, will not be complete. So, when studying metrics of positive scalar curvature on compact manifolds with boundary, it is necessary to impose some sort of a boundary condition. It is natural to require that a metric is a product near the boundary.

Let $M$ be a compact manifold with the boundary $\partial M$. We fix a collar $c: \partial M \times (-1,0) \to M$ and define $\mathcal{R}^+(M)$ to be a space $\{g\}$ of metrics of positive scalar curvature on $M$ such that $c^*(g) = g_0 + dt^2$ on $\partial M \times [-1/4,0]$. We take the usual Fréchet topology on this space. This topology is defined by the collection of $C^k$-norms $\|\cdot\|_k$ on the space of all Riemannian metrics $\mathcal{R}(M^n)$ with respect to some reference metric $h$: $\|g\|_k = \max_{i \leq k} \sup_{M^n} |\nabla^i g|$. The topology does not depend on a choice of the metric $h$.

With this topology $\mathcal{R}^+(M)$ is a Fréchet manifold modeled on the space of symmetric bilinear forms that vanish identically on $c(\partial M \times [-1/4,0])$.

By $\mathcal{R}_0^+(\partial M)$ we denote the image of $\mathcal{R}^+(M)$ under the restriction map

$$\rho: \mathcal{R}^+(M) \to \mathcal{R}^+(\partial M),$$

$$\rho(g) := g|_{\partial M},$$

together with the induced topology. We assume that $\mathcal{R}^+(M)$ is nonempty, which, of course, implies that $\mathcal{R}_0^+(\partial M)$ is nonempty. Since $\mathcal{R}^+(\partial M)$ is locally convex, the

Theorem 1.1. The map $\rho: \mathcal{R}^+(M) \to \mathcal{R}^+_0(\partial M)$ is a quasifibration.

To show that a map between topological spaces $f: X \to Y$ is a quasifibration, it suffices to show that its fiber $f^{-1}(y_0)$ is homotopy equivalent to its homotopy fiber under the canonical inclusion map. The homotopy fiber of $f$ at $y_0 \in Y$ is defined by replacing $f$ by the Serre path fibration $\hat{f}: \hat{X} \to Y$ and taking the fiber $\Omega_{y_0} := \hat{f}^{-1}(y_0)$. Then $\Omega_{y_0} = \{(x, \omega)\}$, where a path $\omega: [0,1] \to Y$ is such that $\omega(0) = f(x)$ and $\omega(1) = y_0$.

The proof of Theorem 1.1 follows from Lemmas 2.2 and 2.3. We introduce an intermediate space $\Omega^*$, which is defined by taking smooth paths $\omega$ in the definition of $\Omega_{y_0}$. Then we show that $\Omega^*$ is homotopy equivalent both to the fiber of $\rho$ and to the homotopy fiber of $\rho$. This implies that the homotopy fiber and the fiber of $\rho$ are homotopy equivalent, and thus completes the proof of Theorem 1.1.

One of the important geometric implications of Theorem 1.1 is Theorem 1.2.

A Hausdorff space $X$ is a topological manifold in the sense of Palais if there exists an open covering $\{O_\alpha\}$ of $X$ and a family of maps $\{\theta_\alpha: O_\alpha \to V_\alpha\}$, where each $V_\alpha$ is a locally convex topological vector space and each $\theta_\alpha$ is a homeomorphism of $O_\alpha$ onto either an open subset of $V_\alpha$ or an open subset of a half space of $V_\alpha$.

Theorem 1.2. Let $A$ be a contractible subset of $\mathcal{R}^+_0(\partial M)$. Suppose that $A$ is a metrizable topological manifold. Then for any point $a \in A$ the inclusion $i: \rho^{-1}(a) \to \rho^{-1}(A)$ is a homotopy equivalence.

Remark 1.1. The conclusion of the above theorem is also true under the assumption that $\rho^{-1}(A)$ is an ANR or, more generally, is dominated by a CW-complex. The author does not know whether these properties follow from $A$ merely being contractible.

In particular, if $h_0$ and $h_1$ are in the same path-connected component of $\mathcal{R}^+_0(\partial M)$, then the spaces of positive scalar curvature metrics that near the boundary restrict to a product with correspondingly $h_0$ and $h_1$ are homotopy equivalent.

Another geometric consequence of Theorem 1.1 is an extension of results in [Che] to manifolds with boundary.

Let $N^{n-k} \subset M^n$, $k \geq 3$, be a submanifold of $M^n$. We assume that there exists a tubular neighborhood $\tau: N \times D^k \to M$, such that the restriction $\tau: \partial N \times D^k \to \partial M$ is a tubular neighborhood of $\partial N$ in $\partial M$. We also assume that the collar $c$ is compatible with $N$ in the sense that its restriction to $\partial N \times (-1,0]$ is a collar for $\partial N$.

We fix a metric $g_N$ on $N$ and a torpedo metric $g_0$ on $D^k$ (a torpedo metric in the disc $D^k$ is an $O(k)$-symmetric, positive scalar curvature metric, which is equal to a $k$-sphere metric near the center of the disc and is a product with a $(k-1)$-sphere metric near the boundary of the disc), such that the metric $g_N + g_0$ has positive scalar curvature on $N \times D^k$. Here the fixed metric $g_N$ can be any metric subject to the only requirement that it is a product near the boundary $\partial N$. 

Let \( h_0 \in \mathcal{R}^+_0(\partial M) \). Since codimension of \( \partial N \) in \( \partial M \) is greater than 2, from Cheeger we may assume that \( \tau^*(h_0) = g_N|_{\partial N} + g_0 \). We define

\[
(\rho^{-1}(h_0))_0 := \{ g \in \rho^{-1}(h_0) | \tau^*(g) = g_N + g_0 \}.
\]

**Theorem 1.3.** Suppose that \( \mathcal{R}^+(M) \) is not empty. Then the inclusion map

\[
i : (\rho^{-1}(h_0))_0 \to \rho^{-1}(h_0)
\]

is a homotopy equivalence.

**Example 1.1.** Let \( M^n \) be a manifold with a \( k \)-handle \( D^{n-k} \times D^k \), such that \( k \geq 3 \) and \( \mathcal{R}^+(M^n) \) is nonempty. Let \( g_1 \) be a metric (which is a product near the boundary) on \( D^{n-k} \) and \( g_0 \) a torpedo metric on \( D^k \), such that \( g := g_1 + g_0 \) has positive scalar curvature. Then for any \( h_0 \in \mathcal{R}^+_0(\partial M) \) the space \( \rho^{-1}(h_0) \) is homotopy equivalent to the subspace of \( \rho^{-1}(h_0) \) consisting of metrics that restrict to the metric \( g \) on the handle. Here the metric \( h_0 \) is obtained by deforming \( h_0 \) to be equal to \( g_1|_{S^{n-k-1}} + g_0 \) on \( S^{n-k-1} \times D^k \subset \partial M \); see Cheeger for details.

## 2. Proofs of the theorems

Given a smooth path of metrics \( \alpha : I \to \mathcal{R}^+(X) \) on a closed smooth manifold \( X \), we would like to put a positive scalar curvature metric on \( X \times \mathbb{R} \). In general, the scalar curvature of the obvious metric \( g(x,t) = \alpha(t)(x) + dt^2 \) will not be positive. However, the metric \( \alpha(t)(x) + adt^2 \) will have positive scalar curvature for all large enough \( a > 0 \). This is a well-known ‘concordance lemma’ of Gromov and Lawson; see GLX80, Ga87.

We show that this concordance can be made to depend continuously on the path \( \alpha \). Here, the topology on the space of paths is the \( C^\infty \)-topology.

We fix a smooth function \( F : \mathbb{R} \to [0,1] \) such that \( 0 \leq F' < 2, F(t) = 0, t \in (-\infty, \epsilon), F(t) = 1, t \in [1-\epsilon, \infty) \), for some \( 0 < \epsilon < 1/4 \), and for a positive number \( \tau \) we define a function \( F_\tau : \mathbb{R} \to \mathbb{R} \), by \( F_\tau(t) = F(\tau t) \).

Let

\[
g_\tau^\alpha(x,t) := \alpha(F_\tau(t))(x) + dt^2.
\]

Define

\[
S'(\alpha) := \inf_{t \geq 0} \{ g_\tau^\alpha \text{ is a psc metric for all } \tau \geq t \},
\]

\[
S(\alpha) := \max(S'(\alpha),1).
\]

The function \( S' : \alpha \mapsto S'(\alpha) \) is upper semi-continuous. Upper semi-continuity (lower semi-continuity) means that we take a topology on \( \mathbb{R} \) generated by the family \( \{ (-\infty,a) \} \) (correspondingly \( \{ (a,\infty) \} \)). By Lemma 2.1 below, it is also lower semi-continuous. It follows that \( S \) is a continuous function of a path.

We define a metric on \( X \times \mathbb{R} \) by the formula

\[
g_\tau^\alpha(x,t) := \alpha(F_\tau_0(t))(x) + dt^2,
\]

where \( t_0 := S(\alpha) \). From the discussion above, this metric depends continuously on the path \( \alpha \). By Lemma 2.1 it has positive scalar curvature and is a Riemannian product near \( X \times 0 \) and \( X \times t_0 \).
Lemma 2.1. Let $\alpha : [0, 1] \to \mathcal{R}^+(X^n)$ be a $C^\infty$-family of positive scalar curvature metrics on a compact closed manifold $X^n$. Then:

(i) $\exists \lambda > 0$ such that $g^\lambda(t) := \alpha(F_\lambda(t)) + dt^2 \in \mathcal{R}^+(X^n \times [0, \lambda])$ and $g^\lambda$ is a product metric near the boundary $(X \times 0) \cup (X \times 1)$ of $X \times [0, \lambda]$;

(ii) if $t_0 = S'(\alpha)$ is a positive number, then $\forall m = 1, 2, \ldots \exists \tau_m > 0$, $x_m \in X^n$, $\tau_m \in [0, t_m]$ such that $t_0 - \frac{1}{m} < t_m < t_0$ and the scalar curvature of $\alpha(F_\lambda(t)) + dt^2$ at $(x_m, \tau_m)$ is negative.

Proof. (i) Denote $g^\lambda(x, t) := \alpha(F_\lambda(t))(x) + dt^2$. Let $(x_0, \tau_0)$ be a point in $X^n \times [0, \lambda]$. Take normal coordinates for $\alpha(F_\lambda(\tau_0))$ at a point $x_0 \in X^n$. In these coordinates, we get $g^\lambda_{ij}(x_0, \tau_0) = \delta_{ij}$, $\Gamma^k_{ij} = 0$ for $1 \leq i, j, k \leq n$. Recall that

$$
\Gamma^k_{ij} = \frac{1}{2}g^{kl}(\partial_l g_{ij} + \partial_j g_{il} - \partial_i g_{lj}).
$$

Since $g^\lambda_{i,n+1} = 0$ for $1 \leq i \leq n$, we get in our normal coordinates at $(x_0, \tau_0)$:

$$
\Gamma^k_{ij}(x_0, \tau_0) = 0 \quad \text{for } 1 \leq i, j, k \leq n,
$$

$$
\Gamma^i_{n+1,j}(x_0, \tau_0) = \frac{1}{2}\partial_n g_{ij}(x_0, \tau_0) \quad \text{for } 1 \leq i, j \leq n,
$$

$$
\Gamma^n_{n+1,i}(x_0, \tau_0) = -\frac{1}{2}\partial_n g_{ij}(x_0, \tau_0) \quad \text{for } 1 \leq i, j \leq n,
$$

and the equations for sectional curvatures are

$$
R^s_{ijk} = \partial_j \Gamma^s_{ik} - \partial_i \Gamma^s_{jk} + \Gamma^l_{ik} \Gamma^s_{jl} - \Gamma^l_{jk} \Gamma^s_{il},
$$

$$
R_{ijkl} = R^s_{ijk}s,
$$

$$
K_{ij} = (\partial_i, \partial_j, \partial_i, \partial_j) = R_{ijij}.
$$

From the Gauss equation for the curvature we get for $1 \leq i, j \leq n$

$$
K_{ij} = K_{ij} + (b_i b_{jj} - b^2_{ij}).
$$

The remaining sectional curvatures are

$$
K_{i,n+1} = R^i_{n+1,i} = \partial_n \Gamma^n_{ii} - \Gamma^n_{i,i} + \Gamma^l_{ii} \Gamma^n_{il} - \Gamma^l_{i} \Gamma^l_{il} - \Gamma^l_{n+1} \Gamma^n_{n+1,l} = -\frac{1}{2}\partial^2_{n+1} g_{ii} - \frac{1}{2}\partial_{n+1} g_{ii}(-\frac{1}{2}\partial_{n+1} g_{ii}) = -\frac{1}{2}\partial^2_{n+1} g_{ii} + \frac{1}{4} \sum_{i=1}^{n+1}(\partial_{n+1} g_{ii})^2.
$$

Then the scalar curvature at a point $(x_0, \tau_0)$ is given by the formula

$$
\kappa = \kappa_X + \sum_{i,j=1}^{n} (b^2_{ij} - b_i b_{jj}) - \sum_{i=1}^{n} \partial^2_{n+1} g_{ii} + \frac{1}{2} \sum_{i,j=1}^{n} (\partial_{n+1} g_{ij})^2.
$$
Now, we have that \( b_{ij} = \Gamma_{ij}^{n+1} = -\frac{1}{2} \partial_{n+1} g_{ij}(x_0, \tau_0) \) and the formulas for the derivatives

\[
\partial_{n+1} g_{ij}(x_0, \tau_0) = \frac{1}{t_0} F'(\tau_0) \alpha' \left( F \left( \frac{\tau_0}{t_0} \right) \right)_{ij}(x_0),
\]

\[
\partial_{n+1}^2 g_{ij}(x_0, \tau_0) = \frac{1}{t_0} F''(\tau_0) \alpha' \left( F \left( \frac{\tau_0}{t_0} \right) \right)_{ij}(x_0) + \frac{1}{t_0^2} (F'(\tau_0))^2 \alpha'' \left( F \left( \frac{\tau_0}{t_0} \right) \right)_{ij}(x_0).
\]

The scalar curvature for the product may now be expressed as

\[
\kappa = \kappa_X + \frac{1}{4} \frac{1}{t_0^2} \sum_{i,j=1}^{n} \left( F' \left( \frac{\tau_0}{t_0} \right) \right)^2 \left( (\alpha'_{ij})^2 - \alpha_{ii} \alpha_{jj} \right)(x_0)
\]

\[
+ \frac{1}{t_0} \sum_{i=1}^{n} \left( F'' \left( \frac{\tau_0}{t_0} \right) \alpha'_{ii}(x_0) + \left( F' \left( \frac{\tau_0}{t_0} \right) \right)^2 \alpha''_{ii}(x_0) \right)
\]

\[
+ \frac{1}{2} \frac{1}{t_0^2} \sum_{i,j=1}^{n} \left( F' \left( \frac{\tau_0}{t_0} \right) \right)^2 \left( \alpha'_{ij}(x_0) \right)^2.
\]

To finish the proof, note that \( \kappa_X \) is positive for all \((x, \tau) \in X^n \times [0, t_0]\).

(ii) Suppose \( t_0 > 0 \) and let \((x_0, \tau_0)\) be a point in \( X^n \times [0, t_0] \) where the scalar curvature is not positive. Such a point always exists since the \( \kappa > 0 \) is an open condition, and if the scalar curvature is everywhere positive we can find \( t_1 < t_0 \) such that the metric corresponding to \( t_1 \) will have positive scalar curvature. Now, freeze the values of \( t_0, \tau_0, \) and \( x_0 \) which are in the arguments for the functions \( F, \alpha \) and their derivatives, and regard the resulting function as a function of the inverse of \( t_0 \). In light of the argument above it has a positive derivative at \( t_0 \) and its value at \( t_0 \) is less or equal than 0. So in an arbitrary neighborhood on the left from \( t_0 \) we can find a value \( t_m \) such that our function will be strictly negative at the point \( t_m \). Now, “unfreezing” only \( \tau_0 \), we can find a number \( \tau_m \) such that \( \frac{\tau_m}{\tau_0} = \frac{t_m}{t_0} \). The point \((x_0, \tau_m)\) is the one that we were seeking.

We fix a metric \( h_0 \in \mathcal{R}^+_0(\partial M) \) and consider the homotopy fiber \( \Omega \) of \( \rho \) at \( h_0 \), \( \Omega = \{(g, \omega) | \omega(0) = \rho(g), \omega(1) = h_0 \} \). The topology on this fiber is the usual compact-open topology. The smooth homotopy fiber \( \Omega^s \) is defined analogously by taking \( \omega \) to be a smooth path. We take the Fréchet topology on the smooth fiber.

There is a natural embedding \( i \) of the fiber \( \rho^{-1}(h_0) \) into \( \Omega^s \), \( i(g) = (g, *) \), where * is the constant path \( *(t) = h_0 \).

**Lemma 2.2.** The map \( i: \rho^{-1}(h_0) \to \Omega^s \) is a homotopy equivalence.

**Proof.** Let \((g, \omega)\) be a point in \( \Omega^s \) and let \( V_0 \) be a constant outward normal vector field on \( \partial M \) of unit length. We take a smooth cutoff function \( \psi \) on \( \mathbb{R} \) with \( \psi(-3/4) = 0, \psi(-1/4) = 1 \), and define a vector field on \( M \) by setting

\[
V(x) = \begin{cases} 
\psi(t)S(\omega)V_0, & x = c(a, t), \\
0, & \text{otherwise},
\end{cases}
\]
where $S$ is defined by formula (1). Extend this vector field to $M \cup (\partial M \times [0, \infty))$ as a constant vector field $S(\omega)V_0$ on $\partial M \times [0, \infty)$ and denote by $\Phi^t_1$ the diffeomorphism determined by the flow of this vector field at $t = 1$. Then $\Phi^1_1(M) = M \cup (\partial M \times [0, S])$. Define

$$g^\omega = \begin{cases} g & \text{on } M, \\ g^\omega_{(0)} & \text{on } \partial M \times [0, S], \\ h_0 & \text{on } \partial M \times [S, \infty), \end{cases}$$

where $g^\omega_{(0)}$ is given by the formula (2).

Now, we define an inverse map $r: \Omega^s \to \rho^{-1}(h_0)$ as

$$r(g, \omega) := \left(\Phi^1_1(\omega)^{s}\right)^*(g^\omega).$$

Here we take the restriction of the pullback metric to $M$.

For $u \in [0, 1]$ we define a path $\omega_u(\tau) := \omega((1-u)\tau + u)$. Let $g^\omega_{(u,F)}$ be the metric that is defined exactly as $g^\omega$ by taking the function $uF$ instead of $F$. The homotopy $H: \Omega^s \times [0, 1] \to \Omega^s$ of $i \circ r$ to the identity map is given by

$$H((g, \omega), u) = \begin{cases} \left(\Phi^1_{2u}S(\omega)\right)^*(g^\omega_{(u,F)}), \omega_0, & 0 \leq u \leq 1/2, \\ \left(\Phi^1_1(\omega)\right)^*(g^\omega_{(2u-1,F)}), \omega_{2u-1}, & 1/2 \leq u \leq 1. \end{cases}$$

When $u$ is equal to 0, the map $H(\cdot, 0)$ is the identity map on $\Omega^s$. When $u = 1$, the map $H(\cdot, 1)$ is equal to $i \circ r$.

**Lemma 2.3.** The inclusion map $i: \Omega^s \to \Omega$ is a homotopy equivalence.

**Proof.** The proof is completely analogous to the proof of Theorem 17.1 in [Mil03]. Since $\Omega$ is an open subset of a locally convex topological vector space, we can cover it with convex open sets. Then take $\Omega_k$, the space of all paths $\omega$ such that $\omega\left(\left(\left\lfloor (j - 1)/2^k \right\rfloor, j/2^k\right)\right)$ is contained in some element of the covering. The space $\Omega$ is a homotopy direct limit of $\Omega_k$, and the space $\Omega^s$ is a homotopy direct limit of $\Omega_k^s := i^{-1}(\Omega_k)$. By Milnor’s argument, the map

$$i|_{\Omega_k^s}: \Omega_k^s \to \Omega_k$$

is a homotopy equivalence. Here, the inverse map is defined by taking a path $\omega \in \Omega_k$ and assigning to it a piecewise linear path that coincides with $\omega$ at points $j/2^k$. Then we smooth the resulting path by pre-composing it with a smooth function that maps $j/2^k$ to $j/2^k$ and all of whose derivatives vanish at points $j/2^k$. This finishes the proof.

**Proof of Theorem 1.2.** If $p: E \to B$ is a quasifibration over a contractible space $B$, then for any point $b \in B$ the inclusion of the fiber $p^{-1}(b) \to E$ induces a weak homotopy equivalence. From Palais [Pal66] we know that both $p^{-1}(a)$ and $p^{-1}(A)$ are dominated by CW-complexes. For such dominated spaces a weak homotopy equivalence is, in fact, a homotopy equivalence by a theorem of J. H. C. Whitehead. From Theorem 1.1 it follows that the inclusion map $i$ is a homotopy equivalence.

**Proof of Theorem 1.3.** As in the proof of Theorem 1.2, it suffices to show that $i$ is a weak homotopy equivalence. In [Che] a method for deforming compact families of metrics of positive scalar curvature was developed, which allowed us to prove the weak homotopy equivalence in the case of closed manifolds $M$ and $N$. This
deformation can be readily adapted to manifolds with boundary and has an important property. Namely, it preserves the product structure with respect to the fixed tubular map \( \tau \), i.e. if \( \tau^*(g) = g_N + g_0 \), then for the deformation metrics \( g(t), t \in [0,1] \), we have \( \tau^*(g(t)) = g_N + g_0(t) \) and \( g(t) \) is constant outside of the tubular neighborhood of \( N \). The problem is that, in general, \( g_0(t) \) is not equal to \( g_0 \), so this deformation takes us outside the fiber \( \rho^{-1}(h_0) \).

The solution is to introduce a subspace \( A \subset \mathcal{R}_0^+(\partial M) \) consisting of metrics that are equal to \( h_0 \) outside \( \tau(\partial N \times D^k) \) and equal to \( g_N|_{\partial N} + g_w \) on \( \tau(\partial N \times D^k) \). Here, \( g_w \) is a warped metric in the disc, i.e. \( g_w = g(t)^2 dt^2 + f(t)^2 d\xi^2 \), where \( d\xi^2 \) is the standard metric of the \((k-1)\)-sphere of radius 1, \( g \) is a smooth even function, and \( f \) is a smooth odd function. Note that \( g_0 \in A \), i.e. a torpedo metric is a warped metric. Then, from the construction of the deformation, we have that \( g_w(t) \) is a warped metric for all \( t \in [0,1] \). This allows us to conclude a weak homotopy equivalence (and, therefore, a homotopy equivalence) between \( (\rho^{-1}(h_0))_0 \) and \( \rho^{-1}(A) \).

From [Che] it follows that the inclusion map \( h_0 \to A \) is a weak deformation retraction; cf. Theorem 4.1 in [Che]. Now, the proof follows from Theorem 1.2.
